**Q1. What is Exception Handling in Python?**

**Ans:**

Exception Handling is a process of handling errors that occur during program execution without stopping the entire program suddenly.

It helps us manage errors and allows the program to continue running smoothly.

Example:

```
a = 10

b = 0

try:

    print(a / b)

except ZeroDivisionError:

    print("Cannot divide by zero")
```

Output:

Cannot divide by zero

Here, Python handles the division error instead of stopping the program.

**Q2. How do you use try, except and finally blocks for handling exceptions in Python?**

**Ans:**

Python uses three important blocks:

1. try: Contains the code that may generate an error.
2. except: Handles the error if it occurs.
3. finally: Executes whether an error occurs or not. It is commonly used for cleanup operations, such as closing files.

Example:

```
try:

    a = 10

    b = 0

    print(a / b)

except ZeroDivisionError:

    print("Cannot divide by zero")
```

```
finally:
    print("Program completed")
```

Output:

Cannot divide by zero

Program completed

**How does it work?**

try block ⟹ Execute risky code

except block ⟹ Handle the error if it occurs

finally block ⟹ Always executes

**Important points to remember**

| **Block** | **Use** |
|---|---|
| try | Checks risky code |
| except | Handles errors |
| finally | Always executes |
